

**Python:-** Python is a **General purpose** programming language.

1. It was developed by **Guido Van Rossum** in **1991**.
2. The latest version of python is **Python 3.14.3** (2026)

#### **Features of Python:-**

1. Easy to learn and analyze
2. High Level programming language
3. Dynamically typed programming language
4. Interpreter based programming language
5. Huge no. of libraries
6. Free and Open Source
7. Platform Independent
8. Large community support

#### **Introduction to Library Functions:-**

**Library Function:-** It is a library which consists of n number of **functions**.

**Function:-** Are nothing but **predefined** things.

**For ex:-** + --> Each of them having some predefined functionality

- -->

\* -->

**len(var):-** It is a function i.e. used to calculate the **no. of values** present in a container.

And it is used with **multivalued datatype** only.

Similar to this, there are many others functions which are predefined whose task are already defined and that function are called as **Library Functions**.

### **There are 3 types of Library Functions:-**

1. Keywords
2. Operators / Special Symbols
3. Inbuilt Functions

#### **Keywords:-**

1. It is a **Universal Standard words** whose task are predefined by the developer and it is fixed.
2. We can **only access** this, but **cannot modify** this.
3. To check keywords -
  - a. `help("keywords")`
  - b. `import keyword`  
`keyword.kwlist`
4. **No. of keywords = 35**
5. **True, False, None --> Special Keywords**
  - a. Starting with the uppercase character
  - b. We can assign this keywords as value also.

#### **Variables:-**

Variable is a name given to particular memory location where we stored the value.

**OR**

It is a container which is used to store the value.

**Syntax:-** `var_name = value`

### **Id() function:-**

1. Used to return the integer address.
2. **Syntax:-** id(val/var\_name)
3. If no. >256 --> different id generated .

### **Multiple Variable Creation:-**

**Example:-** a, b, c, d, e | 10, 20, 30, 10, 20

### **Reference Count**

**Ques:- Can we write anything as variable name?**

### **Identifiers rules:-**

Identifier is a variable which is used to identify the value stored in it.

\* All Variables are identifiers but all identifiers are not variables.

### **Rules of Identifiers:-**

1. Identifier should not be a keyword.
2. It should not start with numbers.
3. It should not contain any special characters except \_.
4. It should not contain space in between or at the beginning.
5. It can have alphabets or alphanumeric but it always start with alphabets or \_
6. According to ISR(Industrial standard rules), it should not cross more than 72 characters limits.

## Datatypes:-

Datatype specify the size and type of value i.e. going to stored in a variable.

Based on size of the value:-

Datatype		
Single valued Datatype		Multi valued Datatype
Numeric	Boolean	
1. Integer 2. Float 3. Complex	1. Bool	1. String 2. List 3. Tuple 4. Set 5. Dictionary

### Single valued Datatype:-

#### 1. Integer:-

Any real no. in range between -inf to +inf without decimal points are called Integer.

**Standard Representation** int

**type(var/val):-** Used to check the standard representation.

#### 2. Float:-

Any real no. with decimal point.

**Standard Representation** float

#### 3. Complex:-

Combination of real and imaginary no.

**Syntax**

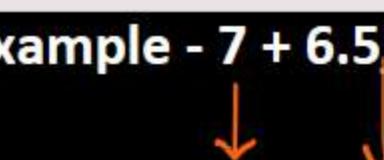

$\pm a \pm bj$

Real Part

Imaginary part ( $j=\sqrt{-1}$ )

Example - 2+6j

Example -  $7 + 6.5j$

Real part      Imaginary part

#### 4. Boolean:-

- It consists of only two types of values i.e. True or False.

True	1
False	0

Standard Representation    bool

#### Multivalued Datatype:-

- String:-

Collection of characters enclosed between ", "", """"""".

Syntax	var = 'val1val2.....valn' var = "val1val2.....valn" var = """val1val2.....valn"""
Standard Representation	str

Example:- s = 'Python 3.14.3@'

#### Indexing:-

Index:- Sub-address provided to each & every element of any collection

- It is used to extract particular characters from a given collection
- It is a sub-address given to each and every block of memory.
- Types of indexing:-

+ve indexing    Traversal from Left to right    Start = 0

-ve indexing

Traversal from Right to left

Start = last index

**Syntax:-**

Var[ index]

**Modification**

Var[ index] = new\_value

4.

\* While doing modification, if controller are not throwing any error -----> **Mutable Collection**

And if error is generated -----> **Immutable Collection**

**Example:-** s = 'Python 3.14.3@'

s[0] = 'A' -----> **TypeError**(str object doesn't support item assignment)

5. Because, String is Immutable Datatype.

## Methods of string:-

### 1. upper()

<b>Use</b>	Converts string to uppercase
<b>Syntax</b>	<code>str.upper()</code>
<b>Args</b>	0
<b>Return</b>	str
<b>Example</b>	"hello".upper() → "HELLO"

### 2. lower()

<b>Use</b>	Converts string to lowercase
<b>Syntax</b>	<code>str.lower()</code>
<b>Args</b>	0
<b>Return</b>	str
<b>Example</b>	"HELLO".lower() → "hello"

### 3. capitalize()

<b>Use</b>	First character uppercase, rest lowercase
<b>Syntax</b>	<code>str.capitalize()</code>
<b>Args</b>	0
<b>Return</b>	str
<b>Example</b>	"python language".capitalize() → "Python language"

### 4. title()

<b>Use:</b>	First letter of each word uppercase
<b>Syntax</b>	<code>str.title()</code>
<b>Args</b>	0
<b>Return</b>	str
<b>Example</b>	"python language".title() → "Python Language"

### 5. isupper()

<b>Use</b>	Checks if all characters are uppercase
<b>Syntax</b>	<code>str.isupper()</code>
<b>Args</b>	0
<b>Return</b>	bool
<b>Example</b>	"HELLO".isupper() → True

### 6. islower()

<b>Use</b>	Checks if all characters are lowercase
<b>Syntax</b>	<code>str.islower()</code>
<b>Args</b>	0
<b>Return</b>	bool

**Example** "hello".islower() → True

## 7. isalpha()

<b>Use</b>	Checks if string contains only alphabets
<b>Syntax</b>	<u>str.isalpha()</u>
<b>Args</b>	0
<b>Return</b>	bool
<b>Example</b>	"Python". <u>isalpha()</u> → True

## 8. isdigit()

<b>Use</b>	Checks if string contains only digits
<b>Syntax</b>	<u>str.isdigit()</u>
<b>Args</b>	0
<b>Return</b>	bool
<b>Example</b>	"123". <u>isdigit()</u> → True

## 9. count()

<b>Use</b>	Counts occurrences of a substring
<b>Syntax</b>	<u>str.count(sub)</u>
<b>Args</b>	1
<b>Return</b>	int
<b>Example</b>	"banana". <u>count("a")</u> → 3

## 10. replace()

<b>Use</b>	Replaces old value with new value
<b>Syntax</b>	<u>str.replace(old, new)</u>

<b>Args</b>	2
<b>Return</b>	str
<b>Example</b>	"hello world".replace("world","python")

## 11. split()

<b>Use</b>	Splits string into list
<b>Syntax</b>	<code>str.split(sep)</code>
<b>Args</b>	0 or 1
<b>Return</b>	list
<b>Example</b>	"a,b,c".split(",") → ['a','b','c']

## 12. strip()

<b>Use</b>	Removes spaces from both ends
<b>Syntax</b>	<code>str.strip()</code>
<b>Args</b>	0
<b>Return</b>	str
<b>Example</b>	" hi ".strip() → "hi"

## 13. lstrip()

<b>Use</b>	Removes spaces from left
<b>Syntax</b>	<code>str.lstrip()</code>
<b>Args</b>	0
<b>Return</b>	str
<b>Example</b>	" hi".lstrip() → "hi"

## 14. rstrip()

#### 14. rstrip()

<b>Use</b>	Removes spaces from right
<b>Syntax</b>	<code>str.rstrip()</code>
<b>Args</b>	0
<b>Return</b>	str
<b>Example</b>	"hi ".rstrip() → "hi"

- **List:-**

- a. Collection of Homogeneous and heterogeneous values which are enclosed between [ ].

►

<b>Homogeneous collection</b>	Same datatype of each value
<b>Heterogeneous collection</b>	Different datatypes collection
<b>Syntax:-</b>	<code>Var = [val, val2, val3, ..., val n]</code>
<b>Standard Representation</b>	list

- c. List is Mutable Datatype

#### Methods of list:-

##### 1. append()

<b>Use</b>	Adds element at the end of list
<b>Syntax</b>	<code>list.append(value)</code>
<b>Args</b>	1
<b>Return</b>	None
<b>Example</b>	[1,2].append(3) → [1,2,3]

##### 2. extend()

<b>Use</b>	Adds multiple elements to list
<b>Syntax</b>	<code>list.extend([value1, value2, value3, ...])</code>

<b>Syntax</b>	<code>list.extend(iterable)</code>
<b>Args</b>	1
<b>Return</b>	None
<b>Example</b>	<code>[1,2].extend([3,4]) → [1,2,3,4]</code>

### 3. `insert()`

<b>Use</b>	Inserts element at given index
<b>Syntax</b>	<code>list.insert(index, value)</code>
<b>Args</b>	2
<b>Return</b>	None
<b>Example</b>	<code>[1,2,3].insert(1,100) → [1,100,2,3]</code>

### 4. `remove()`

<b>Use</b>	Removes first occurrence of value if present otherwise error
<b>Syntax</b>	<code>list.remove(value)</code>
<b>Args</b>	1
<b>Return</b>	None
<b>Example</b>	<code>[1,2,3].remove(2) → [1,3]</code>

### 5. `pop()`

<b>Use</b>	Removes element using index
<b>Syntax</b>	<code>list.pop(index)</code>
<b>Args</b>	0 or 1
<b>Return</b>	removed element
<b>Example</b>	<code>[1,2,3].pop() → 3</code>

## 6. clear()

<b>Use</b>	Removes all elements from list
<b>Syntax</b>	<code>list.clear()</code>
<b>Args</b>	0
<b>Return</b>	None
<b>Example</b>	<code>[1,2].clear() → []</code>

## 7. index()

<b>Use</b>	Returns index of given value if present otherwise error
<b>Syntax</b>	<code>list.index(value)</code>
<b>Args</b>	1
<b>Return</b>	int
<b>Example</b>	<code>[10,20,30].index(20) → 1</code>

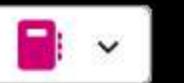

## 8. count()

<b>Use</b>	Counts occurrences of value
<b>Syntax</b>	<code>list.count(value)</code>
<b>Args</b>	1
<b>Return</b>	int
<b>Example</b>	<code>[1,1,2].count(1) → 2</code>

## 9. sort()

<b>Use</b>	Sorts list in ascending order
<b>Syntax</b>	<code>list.sort()</code>
<b>Args</b>	0
<b>Return</b>	None

<b>Example</b>	a = [3, 1, 2] a.sort() print(a) → [1,2,3]
----------------	--

### 10. reverse()

<b>Use</b>	Reverses the list
<b>Syntax</b>	list.reverse()
<b>Args</b>	0
<b>Return</b>	None
<b>Example</b>	[1,2,3].reverse() → [3,2,1]

## 3. Tuple:-

- a. Collection of Homogeneous and heterogeneous values which are enclosed between ().

<b>Homogeneous collection</b>	Same datatype of each value
<b>Heterogeneous collection</b>	Different datatypes collection
<b>b. Syntax:-</b>	Var = (val, val2, val3, ...., val n)
<b>Standard Representation</b>	tuple
<b>Example</b>	t = (10, 20.5, 'Python', True)

- c. Tuple is Immutable Datatype

### Methods of Tuple:-

#### i. count()

<b>Use</b>	Counts occurrences of a value
<b>Syntax</b>	tuple.count(value)
<b>Args</b>	1
<b>Return</b>	.

Args	1
Return	int
Example	(1,2,2,3).count(2) → 2

## ii. index()

Use	Returns index of first occurrence of value
Syntax	tuple.index(value)
Args	1
Return	int
Example	(10,20,30).index(20) → 1

## 4. Dictionary:-

- a. It is used to store the multiple values in the form of key-value pairs.
- b. **Syntax** Var = {key1:val1, key2:val2, key3:val3, ..., keyn:valn}
- c. Key and value are separated by the :(colon) and the whole element is separated by ,(comma).
- d. Indexing and slicing is not present in dictionary.
- e. Key should be unique, immutable value and acts as index.

<b>Standard representation</b>	dict
<b>Default value</b>	{}

- g. There are 2 layers in dictionary -

<b>Key Layer</b>	Only visible
<b>Value Layer</b>	Hidden

## Methods of dictionary:-

- i. get()

### i. get()

<b>Use</b>	Returns value for given key (no error if key not found)
<b>Syntax</b>	dict.get(search_key, default_value)
<b>Args</b>	1 or 2
<b>Return</b>	value / None
<b>Example</b>	{"a":10,"b":20}.get("a") → 10

### ii. keys()

<b>Use</b>	Returns all keys of dictionary
<b>Syntax</b>	dict.keys()
<b>Args</b>	0
<b>Return</b>	dict_keys
<b>Example</b>	{"a":10,"b":20}.keys() → dict_keys(['a','b'])

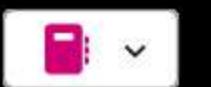

### iii. values()

<b>Use</b>	Returns all values of dictionary
<b>Syntax</b>	dict.values()
<b>Args</b>	0
<b>Return</b>	dict_values
<b>Example</b>	{"a":10,"b":20}.values() → dict_values([10,20])

### iv. items()

▶ <b>Use</b>	Returns key-value pairs as tuples
<b>Syntax</b>	dict.items()
<b>Args</b>	0
<b>Return</b>	dict_items

**Example** {"a":10,"b":20}.items() → dict\_items([('a',10),('b',20)])

### v. pop()

<b>Use</b>	Removes and returns value of given key
<b>Syntax</b>	dict.pop(key)
<b>Args</b>	1
<b>Return</b>	value
<b>Example</b>	{"a":10,"b":20}.pop("a") → 10

### vi. clear()

<b>Use</b>	Removes all elements from dictionary
<b>Syntax</b>	dict.clear()
<b>Args</b>	0
<b>Return</b>	None
<b>Example</b>	d = {"a":10}; d.clear() → {}

**Ques: Difference between mutable datatype and immutable datatype?**

## 5. Set:-

- a. It is an unordered and mutable collection of immutable values i.e. stored in {}.
- b. Indexing and Slicing can't be performed because it is unordered.
- c. Keeps only unique values.
- d. It can only store - int, float, complex, bool, str, tuple.

<b>Standard Representation</b>	set()
<b>Default Value</b>	set()

## Methods of Set:-

### i. add()

<b>Use</b>	Adds an element to the set
<b>Syntax</b>	<code>set.add(value)</code>
<b>Args</b>	1
<b>Return</b>	None
<b>Example</b>	<code>s = {1,2}; s.add(3) → {1,2,3}</code>

### ii. copy()

<b>Use</b>	Returns a copy of the set
<b>Syntax</b>	<code>set.copy()</code>
<b>Args</b>	0
<b>Return</b>	set
<b>Example</b>	<code>s = {1,2}; s.copy() → {1,2}</code>

### iii. pop()

<b>Use</b>	Removes and returns a random element
<b>Syntax</b>	<code>set.pop()</code>
<b>Args</b>	0
<b>Return</b>	element
<b>Example</b>	<code>{1,2,3}.pop() → 1 (any element)</code>

### iv. remove()

<b>Use</b>	Removes specified element (error if not found)
<b>Syntax</b>	<code>set.remove(value)</code>
<b>Args</b>	1
<b>Return</b>	None

**Example** {1,2,3}.remove(2) → {1,3}

...

#### v. **discard()**

<b>Use</b>	Removes specified element (no error if not found)
<b>Syntax</b>	<code>set.discard(value)</code>
<b>Args</b>	1
<b>Return</b>	None
<b>Example</b>	{1,2,3}.discard(5) → {1,2,3}

**Operator:-** Used to perform operation on operands

#### Types of Operator:-

- 1. Arithmetic Operator** (+, -, \*, %, //, \*\*)
- 2. Logical Operator** (or, not, and)
- 3. Assignment Operator** (=, +=, -=, \*=, /=, //=, %=, \*\*=)
- 4. Relational Operator** (<, >, <=, >=, ==, !=)
- 5. Membership Operator** (in, not in)
- 6. Bitwise Operator** (&, |, ~, ^, <<, >>)
- 7. Identity Operator** (is, is not)

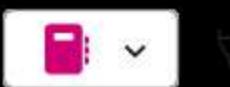

#### 1. Arithmetic Operators (+, -, \*, %, //, \*\*)

a = 10

b = 3

```
print(a + b) # Addition → 13
print(a - b) # Subtraction → 7
print(a * b) # Multiplication → 30
print(a % b) # Modulus (remainder) → 1
```

```
print(a * b) # Multiplication → 30  
print(a % b) # Modulus (remainder) → 1  
print(a // b) # Floor division → 3  
print(a ** b) # Exponentiation → 1000
```

## 2. Logical Operators (and, or, not)

```
x = True
```

```
y = False
```

```
print(x and y) # True if both are True → False  
print(x or y) # True if any one is True → True  
print(not x) # Negation → False
```

## 3. Assignment Operators (=, +=, -=, \*=, /=, //=, %=, \*\*=)

```
c = 10      # Assignment  
c += 5      # c = c + 5 → 15  
c -= 2      # c = c - 2 → 13  
c *= 2      # c = c * 2 → 26  
c /= 2      # c = c / 2 → 13.0  
c //= 2     # c = c // 2 → 6.0  
c %= 4      # c = c % 4 → 2.0  
c **= 3     # c = c ** 3 → 8.0  
print(c)
```

## 4. Relational Operators (<, >, <=, >=, ==, !=)

```
p = 5
```

```
q = 10
```

```
print(p < q) # Less than → True
```

#### 4. Relational Operators (`<`, `>`, `<=`, `>=`, `==`, `!=`)

```
p = 5  
q = 10  
  
print(p < q) # Less than → True  
print(p > q) # Greater than → False  
print(p <= q) # Less than or equal → True  
print(p >= q) # Greater than or equal → False  
print(p == q) # Equal to → False  
print(p != q) # Not equal to → True
```

#### 5. Membership Operators (`in`, `not in`)

```
lst = [1, 2, 3, 4]
```

```
► print(2 in lst) # Checks if 2 exists in list → True  
print(5 not in lst) # Checks if 5 not in list → True
```

#### 6. Bitwise Operators (`&`, `|`, `~`, `^`, `<<`, `>>`)

```
m = 5 # 0101  
n = 3 # 0011
```

```
print(m & n) # AND → 1  
print(m | n) # OR → 7  
print(~m) # NOT → -6  
print(m ^ n) # XOR → 6  
print(m << 1) # Left shift → 10  
print(m >> 1) # Right shift → 2
```

#### 7. Identity Operators (`is`, `is not`)

## 7. Identity Operators (is, is not)

```
r = [1, 2, 3]  
s = r # [1, 2, 3]  
t = [1, 2, 3]
```

```
print(r is s)    # Same object → True  
print(r is t)    # Different object → False  
print(r is not t) # Not same object → True
```

**input():** Used to get input from the user.

Syntax	var = input("msg")
--------	--------------------

- i. Always considers the input in the form of string.
- ii. Using input(), we cannot directly insert tuple, list, dict, or set.

To overcome this issue, eval() is used.

## eval():

Used to take user input and automatically convert it into its actual datatype.

Syntax	var = eval(input("msg"))
--------	--------------------------

Example	var = eval(input("Enter value: "))
---------	------------------------------------

Input → [1,2,3,4]

Output → [1, 2, 3, 4]

## Control Flow Statements:-

1. It is used to control the flow of execution of program.

2. **Types:-**

- a. Decisional / Conditional Control Statements (if, if-else, elif, nested-if)
- b. Looping Control Statements (while, for)

## Decisional / Conditional Control Statements:-

These are the statements which is used to perform some operation --> **condition** --> if satisfied

### a. Normal If

marks = 75

```
if marks >= 40:  
    print("Pass")
```

### b. if - else

marks = 75

```
if marks >= 40:  
    print("Pass")  
else:  
    print("Fail")
```

### c. elif

marks = 75

```
if marks >= 75:  
    print("Distinction")  
elif marks >= 40:  
    print("Pass")  
else:  
    print("Fail")
```

### d. nested if

marks = 75

```
if marks >= 40:  
    if marks >= 75:
```

```
print("Pass with Distinction")
else:
    print("Pass")
else:
    print("Fail")
```

## Looping Control Statements:-

These are the statements which is used to perform some task repeatedly.

### a. WHILE LOOP:-

- Used to perform some task again and again until the given condition satisfied.
- No. of iterations are not known
- It will not works with set and dictionary
- **Syntax:**

Initialization

while condition:

Updation

- Initialization & Updation are mandatory.
- Example 1:- While loop **without updation**

```
j = 1 # Initialization
```

```
while j <= 5:
    print(i)
```

- Example 2:- While loop **with updation**

```
j = 1 # Initialization
```

```
while j <= 5:
    print(i)
```

- Example 2:- While loop **with updation**

```
j = 1 # Initialization
```

```
while j <= 5:  
    print(i)  
    i = i + 1 # Updation
```

## b. FOR LOOP:-

- For loops works with any of the collection datatype
- By default, for loops go till the length of the collection and iterate over each values.
- **Syntax:-**

```
for var in collection:
```

- **Examples (for loop)**

```
for i in range(1, 6):  
    print(i)
```

```
for ch in "Python":  
    print(ch)
```

- **range():-**

1. range() is used to generate a sequence of numbers.
2. Does **not store values**, it generates them one by one

**Syntax:** range(start, stop, step)

- start → starting value (default = 0)

- stop → ending value (excluded)
- step → increment/decrement (default = 1)

### Examples (range):-

```
print(list(range(5)))
print(list(range(1, 10, 2)))
```

### Transfer Control Statements:-

1. <b>break:</b>	Terminated the execution of a loop
2. <b>continue</b>	Used to skip rest of the code
3. <b>pass</b>	Used as a <b>null statement</b> when no action is required

### Code for break:-

```
for i in range(1, 6):
    if i == 3:
        break
    print(i)
```

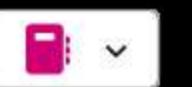

### Code for continue-

```
for i in range(1, 6):
    if i == 3:
        continue
    print(i)
```

### Code for pass:-

## Code for pass:-

```
def main():
    pass
```

## Slicing:-

Slicing is a process where we are extracting a group of characters from collections.

**Syntax** var[start\_idx: end\_idx: updation]

By default,

updation (step)	1
• Left → Right	end_idx + 1
Right → Left	end_idx - 1

## String Slicing Example:-

```
s = "BVRIT College"
```

```
s[0:5]
```

```
s[6:12]
```

## Reverse the string

```
s[::-1]
```

## Skip 1 character from "College"

```
s[6:13:2]
```

## Tuple Example:-

```
st = ('Indore', 'Pune', 'Goa', 'Delhi')
```

```
st[-4:-1]
```

## Nested Tuple
